PROTEIN PROTEIN INTERACTION ANALYSIS IS A CORNERSTONE OF MODERN MOLECULAR BIOLOGY THAT ALLOWS SCIENTISTS TO DECIPHER THE COMPLEX WEB OF INTERACTIONS THAT UNDERPIN VIRTUALLY EVERY CELLULAR PROCESS. PROTEINS RARELY ACT ALONE; INSTEAD, THEY ENGAGE IN DYNAMIC PARTNERSHIPS THAT GOVERN EVERYTHING FROM SIGNAL TRANSDUCTION AND METABOLIC PATHWAYS TO STRUCTURAL INTEGRITY AND IMMUNE RESPONSES. protein protein interaction analysis: Graph-based Analysis of Protein-protein

Interaction Data Sets, 2007 High-throughput methods for detecting protein-protein interactions (PPI) have recently gained popularity. These rapid advances in technology have given researchers an initial global picture of protein interactions on a genomic scale. The usefulness of this understanding is, however, typically compromised by noisy data and intrinsic complexity of the biological system. In this dissertation, we attempt to solve some problems in effectively analyzing the data. Firstly, since there are lots of false positives in experimentally detected interactions, we propose a novel topological measurement to select reliable interactions from the noisy data. Our method is based on the small-world network property of the protein interaction network and generalizes purely local measures adopted previously. Based on our observation that the true positive interactions in protein complexes and tightly coupled networks demonstrate dense interactions, we propose to measure the significance of two proteins' co-existence in a dense network as an index of interaction reliability. Our topological measure also integrates the prior confidence of each data set. The experiments demonstrate that our measure can be used to identify reliable interactions and to predict potential interactions with improved performance. Meanwhile, we discovered two additional properties: namely, the short alternative path property and the local clustering of network property of the protein interaction network, which are generalizations of previously known protein interaction network properties. Secondly, we address the problem of effectively incorporating domain knowledge into the protein clustering process. Based on our analysis of the relationship of network topology and biological relevance, we propose a novel semi-supervised clustering algorithm suitable for the noisy protein interaction network. We choose to estimate the pairwise similarity between each protein pair and use this similarity as input to clustering algorithms. Therefore, it is not bounded to any specific clustering methods. We select topological features in the network and define a model to map these features to pairwise similarities. The known protein annotations are used to train the model. Using this model, we can estimate the pairwise similarity between each pair of proteins. Finally, normal unsupervised clustering algorithms can be applied using the similarity matrix. Since our similarity measure has already incorporated prior protein annotations, our algorithm can detect clusters with improved performance. Also, the unsupervised clustering algorithms we adopt maintain the explorative nature and therefore are capable of detecting new protein functional groups. Thirdly, we investigate the problem of protein complex detection. Protein complexes can be roughly considered as densely connected subgraphs in the network. The difficulties in this problem are caused by the fact that protein complexes may overlap with each other, i.e. containing shared proteins, and the protein interaction network contains a lot of noise. To overcome these difficulties, we propose a novel subgraph quality measure, and based on the measure, we propose a novel seed-refine algorithm. Our subgraph quality measure achieves two goals: (1) it provides a statistically meaningful combination of inside links, outside links and the size of the subgraph and, (2) it provides a statistically meaningful combination of the quality contribution of each vertex in the subgraph. Our seed-refine algorithm consists of a two-layer seeding heuristic to find good seeds and a novel subgraph refinement method that controls the overlap between subgraphs. Our algorithm allows to output overlapping subgraphs but methodologically makes it possible only when there is strong evidence to do so. Experiments confirm the effectiveness of our method.

protein protein interaction analysis: Protein-Protein Interactions Haian Fu, 2008-02-03 As the mysteries stored in our DNA have been more completely revealed, scientists have begun to face the extraordinary challenge of unraveling the intricate network of protein-protein interactions established by that DNA framework. It is increasingly clear that proteins continuously interact with one another in a highly regulated fashion to determine cell fate, such as proliferation, differentiation, or death. These protein-protein interactions enable and exert stringent control over DNA replication, RNA transcription, protein translation, macromolecular assembly and degradation, and signal transduction; essentially all cellular functions involve protein-protein interactions. Thus, protein-protein interactions are fundamental for normal physiology in all organisms. Alteration of critical protein-protein interactions is thought to be involved in the development of many diseases, such as neurodegenerative disorders, cancers, and infectious diseases. Therefore, examination of when and how protein-protein interactions occur and how they are controlled is essential for understanding diverse biological processes as well as for elucidating the molecular basis of diseases and identifying potential targets for therapeutic interventions. protein protein interaction analysis: Protein-protein Interaction Confidence Assessment and Network Clustering Computational Analysis Mathieu Lavallée-Adam, 2014 Protein-protein interactions represent a crucial source of information for the understanding of the biological mechanisms of the cell. In order to be useful, high quality protein-protein interactions must be computationally extracted from the noisy datasets produced by high-throughput experiments such as affinity purification. Even when filtered protein-protein interaction datasets are obtained, the task of analyzing the network formed by these numerous interactions remains tremendous. Protein-protein interaction networks are large, intricate, and require computational approaches to provide meaningful biological insights. The overall objective of this thesis is to explore algorithms assessing the quality of protein-protein interactions and facilitating the analysis of their networks. This work is divided into four results: 1) a novel Bayesian approach to model contaminants originating from affinity purifications, 2) a new method to identify and evaluate the quality of protein-protein interactions independently in different cell compartments, 3) an algorithm computing the statistical significance of clusterings of proteins sharing the same functional annotation in protein-protein interaction networks, and 4) a computational tool performing sequence motif discovery in 5' untranslated regions as well as evaluating the clustering of such motifs in protein-protein interaction networks. --

protein protein interaction analysis: Applications of Chimeric Genes and Hybrid Proteins, Part C: Protein-Protein Interactions and Genomics , 2000-10-28 The critically acclaimed laboratory standard for more than forty years, *Methods in Enzymology* is one of the most highly respected publications in the field of biochemistry. Since 1955, each volume has been eagerly awaited, frequently consulted, and praised by researchers and reviewers alike. Now with more than 300 volumes (all of them still in print), the series contains much material still relevant today--truly an essential publication for researchers in all fields of life sciences.

protein protein interaction analysis: *Systems Biology Approaches for Host-Pathogen Interaction Analysis* Mohd. Tashfeen Ashraf, Abdul Arif Khan, Fahad M. Aldakheel, 2024-02-16 System Biology Approaches for Microbial Pathogenesis Interaction Analysis aids biological researchers to expand their research scope using piled up data generated through recent technological advancement. In addition, it also opens avenues for bioinformatics and computer science researchers to utilize their expertise in biological meaningful ways. It also covers network biology approaches to decipher complex multiple host-pathogen interactions in addition to giving valuable coverage of artificial intelligence. The host-pathogen interactions are generally considered as highly specific interactions leading to a variety of consequences. The utilization of data science approaches has revolutionized scientific research including host-pathogen interaction analyses. Data science approaches coupled with network biology has taken host-pathogen interaction analysis from specific interaction to a new paradigm of understanding consequences of these interaction in the biological network. Unfortunately, basic biological researchers are mostly unaware of these advancements. In contrast, data scientists are not familiar with biological aspects of such data. System Biology Approaches for Microbial Pathogenesis Interaction Analysis will bridge these gaps through a new paradigm of understanding consequences of interaction in biological networks. - Cover approaches to decipher complex multiple host-pathogen interactions - Gives biological researcher an insight into the utilization of technological advancements in the field of host-pathogen interaction analyses in their work - Provides a new paradigm of understanding the consequences of host-pathogen interaction in biological systems
